

**i need to develop a WAAP where i will develop a module for API security.so give me rule set for the owasp top 10 API vulnerability. i need the exact working rule set in python for the API security .**

Here is a practical, production-grade Python rule set you can drop into a WAAP (reverse proxy/middleware) to mitigate the OWASP API Security Top 10 (2023). It implements request/response validation, authentication, authorization (object, property, and function level), rate limiting and burst control, anti-automation on sensitive business flows, SSRF egress control, security headers, schema-based allow-lists, version/inventory enforcement, and upstream API hardening. The categories and controls map to OWASP's 2023 API Top 10 list and recommended mitigations. Adapt the stubbed policy callbacks to your identity store, RBAC/ABAC engine, schemas, and data layer. What this enforces (mapping to OWASP API Top 10 2023):

- API1 Broken Object Level Authorization: Ownership checks per route, using path params to enforce BOLA on read/write. [\[4\]](#) [\[5\]](#) [\[1\]](#)

- API2 Broken Authentication: Bearer token required by default, issuer/audience checks, and a stub for real JWKS verification; tie into IdP/OIDC in production. [\[9\]](#) [\[10\]](#) [\[1\]](#) [\[4\]](#)
- API3 Broken Object Property Level Authorization: Request schema allow-listing to prevent mass assignment; response field filtering via PROPERTY\_ACL to avoid excessive data exposure. [\[3\]](#) [\[5\]](#) [\[1\]](#) [\[4\]](#)
- API4 Unrestricted Resource Consumption: Token bucket rate limiting per identity+path; body size limits, JSON depth/collection limits, and method gating. [\[10\]](#) [\[1\]](#) [\[3\]](#) [\[9\]](#)
- API5 Broken Function Level Authorization: Role gates per method+route for admin vs user operations. [\[1\]](#) [\[4\]](#) [\[9\]](#)
- API6 Unrestricted Access to Sensitive Business Flows: Anti-automation heuristics on ticket/purchase flows; extend with challenges/fingerprints. [\[6\]](#) [\[3\]](#) [\[1\]](#)
- API7 Server-Side Request Forgery: Safe egress client with host allow-list, scheme restrictions, and private-IP blocking before making outbound requests. [\[8\]](#) [\[3\]](#) [\[10\]](#) [\[1\]](#)
- API8 Security Misconfiguration: Security headers, disallowed HTTP verbs, basic key blacklist, strict JSON parsing, and default-deny endpoints. [\[7\]](#) [\[9\]](#) [\[1\]](#)
- API9 Improper Inventory Management: Version gating, deprecated version blocking, and documented-endpoint allow-list. [\[3\]](#) [\[10\]](#) [\[1\]](#)
- API10 Unsafe Consumption of APIs: Validate upstream responses, minimize fields, and never trust third-party payloads without schema checks. [\[8\]](#) [\[9\]](#) [\[1\]](#) [\[3\]](#)

## Integration notes

- Authentication: Replace fake\_verify\_jwt with standards-based verification (OIDC discovery + JWKS, token lifetime checks, nonce/at\_hash as needed). [\[4\]](#) [\[9\]](#) [\[10\]](#)
- Authorization: Swap FUNCTION\_ROLE\_MAP and PROPERTY\_ACL for centralized ABAC/RBAC policies; log all denials for forensics. [\[1\]](#) [\[4\]](#)
- Rate limiting: Back with Redis/cluster to enforce globally; consider per-scope and per-endpoint weights; add concurrency caps and timeouts. [\[9\]](#) [\[3\]](#)
- SSRF: If you host egress in a separate microservice, still enforce DNS pinning and disallow redirects to private IP; add URL normalization and block IPv6 literals if not needed. [\[10\]](#) [\[8\]](#) [\[1\]](#)
- Schemas: Use OpenAPI-derived Pydantic models to generate ALLOWED\_REQUEST\_SCHEMAS automatically for tight allow-listing. [\[5\]](#) [\[3\]](#) [\[4\]](#)
- Security headers and CORS: Add strict CORS rules per audience; include HSTS at the edge/ingress. [\[7\]](#) [\[9\]](#) [\[10\]](#)
- Inventory: Fail closed on undocumented routes; use spec linting in CI to ensure DOCUMENTED\_ENDPOINTS and version policy stay current. [\[3\]](#) [\[10\]](#) [\[1\]](#)

## explain all the codes above in detail

The module implements a WAAP-style middleware that enforces controls mapped directly to the OWASP API Security Top 10 (2023) by inspecting every request/response, authenticating callers, authorizing functions, objects, and properties, rate-limiting, constraining payload resources, protecting sensitive flows from automation, restricting egress to prevent SSRF, enforcing security headers, and gating versions/endpoints to ensure proper API inventory. Each control aligns with OWASP's 2023 list and its recommended mitigations for API1-API10. [\[39\]](#)

### High-level structure

- Policy/config blocks define which API versions/endpoints are allowed, who can call which functions, what properties are exposed, rate limits, security headers, and SSRF allow-lists; these are the "rules" the middleware enforces on every request and select responses. [\[39\]](#)
- Schemas (Pydantic) act as allow-lists to prevent mass assignment and overposting and ensure only explicit fields are accepted per route. [\[39\]](#)
- The WAAP middleware sits in front of your FastAPI app, failing closed by default for undocumented or deprecated versions and injecting security headers on all responses. [\[39\]](#)
- Dedicated egress client validates destination URLs before any server-side call, blocking private networks and non-allow-listed hosts to mitigate SSRF. [\[39\]](#)

### Constants and policy sources

- `ALLOWED_API_VERSIONS`, `DEPRECATED_VERSIONS`, and `DOCUMENTED_ENDPOINTS` implement inventory/version controls so only documented, current surfaces respond; deprecated versions return 410 and unknown versions 404, limiting shadow and zombie APIs. This addresses Improper Inventory Management (API9). [\[39\]](#)
- `SENSITIVE_BUSINESS_FLOWS` enumerates critical flows (e.g., ticket purchase, payments) to apply anti-automation heuristics, covering Unrestricted Access to Sensitive Business Flows (API6). [\[39\]](#)
- `FUNCTION_ROLE_MAP` ties method+route to allowed roles to enforce distinct function-level permissions (e.g., admin-only PATCH), addressing Broken Function Level Authorization (API5). [\[39\]](#)

- PROPERTY\_ACL defines which response fields are visible per role; coupled with request schema allow-lists, this prevents excessive data exposure and mass assignment, handling Broken Object Property Level Authorization (API3). [\[39\]](#)
- OBJECT\_OWNERSHIP\_FIELDS provides per-route lambdas that verify the principal owns the resource or has privileged role, closing Broken Object Level Authorization/BOLA (API1). [\[39\]](#)
- RATE\_LIMITS defines per-path limits with a token bucket (limit/window/burst), plus MAX\_BODY\_BYTES, MAX\_ARRAY\_LENGTH, and MAX\_DEPTH to cap resource use, addressing Unrestricted Resource Consumption (API4). [\[39\]](#)
- EGRESS\_SSRF\_ALLOWLIST and BLOCK\_PRIVATE\_EGRESS restrict outbound destinations by host and scheme, and block private/loopback, mitigating Server-Side Request Forgery (API7). [\[39\]](#)
- SECURITY\_HEADERS and REJECT\_HTTP\_METHODS enforce response hardening (e.g., X-Content-Type-Options, CSP) and deny risky verbs (TRACE/TRACK/CONNECT), countering Security Misconfiguration (API8). [\[39\]](#)
- REJECT\_QUERY\_KEYS blacklists dangerous keys often abused in prototype pollution or server-side injection, contributing to API hardening and misconfiguration defenses (API8). [\[39\]](#)
- JWT\_ISSUERS and JWT\_AUDIENCE define acceptable token issuers/audience; fake\_verify\_jwt is a stub to be replaced by standard OIDC/JWKS validation for Broken Authentication (API2). [\[39\]](#)

## Schemas and mass assignment defense

- UserPatch permits only the email field on PATCH /v1/users/{id}; ALLOWED\_REQUEST\_SCHEMAS maps routes to models, ensuring only whitelisted properties pass validation and others are rejected, stopping overposting/mass assignment and preventing exposure via property-level authorization (API3). [\[39\]](#)

## Helper functions

- route\_key normalizes paths by replacing ID-like segments with {id} so rules match templated routes; extract\_path\_params recovers dynamic path variables for object ownership checks (API1/5). [\[39\]](#)
- deep\_limits traverses JSON to enforce depth and collection-size caps, preventing resource exhaustion and parsing bombs (API4). [\[39\]](#)
- is\_private\_ip resolves host A records and blocks private/loopback/link-local/multicast/reserved ranges to fail closed on private targets for SSRF controls (API7). [\[39\]](#)
- hash\_identity combines client IP and subject claim into a stable token for rate limiting; TokenBucket implements burst and steady refill; check\_rate\_limit ties it together per identity+path (API4). [\[39\]](#)

## WAAP middleware pipeline

- Method filtering: blocks TRACE/TRACK/CONNECT up front for safer defaults (API8). [\[39\]](#)
- Version and surface gating: enforces version policy and rejects undocumented endpoints with 404, preventing accidental exposures and shadow routes (API9). [\[39\]](#)
- Authentication: requires Bearer tokens by default, except explicit public routes like login; validates issuer and audience, and returns 401 for invalid/missing tokens, addressing Broken Authentication (API2). [\[39\]](#)
- Rate limiting and resource control: computes an identity key and enforces token bucket limits; checks payload size before parsing to reduce DoS risk (API4). [\[39\]](#)
- Strict JSON handling: decodes JSON with error handling, applies deep\_limits, and rejects disallowed query keys to reduce misconfig/injection surface (API4/API8). [\[39\]](#)
- Schema allow-listing: validates and rewrites the request body to only allowed fields; Pydantic errors cause a 400 with detail, preventing mass assignment and property-level misuse (API3). [\[39\]](#)
- Function-level authorization: checks role membership against FUNCTION\_ROLE\_MAP and returns 403 if forbidden (API5). [\[39\]](#)
- Object-level authorization: for routes with IDs, enforces ownership/privilege checks from OBJECT\_OWNERSHIP\_FIELDS and returns 403 if access is not allowed (API1). [\[39\]](#)
- Anti-automation on sensitive flows: applies simple user-agent heuristic to throttle likely bots on flows like payments; extendable to challenges/fingerprints (API6). [\[39\]](#)
- Response security headers: wraps send to add standard security headers on every response, reducing attack surface from clickjacking/MIME sniffing/referrer leakage (API8). [\[39\]](#)
- State propagation: attaches principal and sanitized\_json\_body to scope.state so downstream handlers consume sanitized input and caller identity consistently (cross-cutting). [\[39\]](#)

## Example upstream handlers

- get\_user filters response fields based on PROPERTY\_ACL and caller role; hidden fields like passwordHash never leave the service for non-admins, handling property-level authorization (API3). [\[39\]](#)
- patch\_user uses sanitized\_json\_body from the middleware so only allowed fields are applied; then filters output by role (API3). [\[39\]](#)
- login stays unauthenticated by design as a public route and returns 501 placeholder; in real systems, this is delegated to an IdP/OIDC flow to avoid building custom auth (API2). [\[39\]](#)

## SafeEgressClient (SSRF and API10)

- Validates outbound URL scheme and host; blocks private addresses and denies non-allow-listed hosts or scheme mismatches, preventing SSRF pivots to internal metadata services and network scans (API7).<sup>[39]</sup>
- Payment example calls an allow-listed upstream (e.g., Stripe) and then validates the returned shape, returning minimal fields to the client; this avoids trusting third-party responses blindly and reduces blast radius from compromised partners, addressing Unsafe Consumption of APIs (API10).<sup>[39]</sup>

## OWASP API Top 10 mapping summary

- API1 Broken Object Level Authorization: Per-route ownership checks using path params deny cross-tenant/object access with 403.<sup>[39]</sup>
- API2 Broken Authentication: Default-deny unauthenticated requests; issuer/audience validation; replace stub with OIDC/JWKS to harden token verification.<sup>[39]</sup>
- API3 Broken Object Property Level Authorization: Request schema allow-lists plus response field ACLs prevent overposting and sensitive field leakage.<sup>[39]</sup>
- API4 Unrestricted Resource Consumption: Token-bucket rate limits per identity+path, body size caps, depth/array bounds, and restricted methods.<sup>[39]</sup>
- API5 Broken Function Level Authorization: Route-level role gates for admin/support vs. customer-only endpoints.<sup>[39]</sup>
- API6 Unrestricted Access to Sensitive Business Flows: Extra throttling/heuristics on business-critical flows to deter automated abuse even without a code bug.<sup>[39]</sup>
- API7 Server-Side Request Forgery: DNS-based private IP detection, host allow-list, scheme restrictions, and closed-by-default egress.<sup>[39]</sup>
- API8 Security Misconfiguration: Secure headers, rejected dangerous verbs, strict parsing and key blacklists, and default-deny on undocumented endpoints.<sup>[39]</sup>
- API9 Improper Inventory Management: Version gating, deprecation blocking, and a curated set of documented endpoints that fail closed.<sup>[39]</sup>
- API10 Unsafe Consumption of APIs: Upstream response validation and minimization, never trusting third-party payloads implicitly.<sup>[39]</sup>

## How to adapt for production

- Replace fake\_verify\_jwt with standards-based verification: OIDC discovery, JWKS caching/rotation, clock skew checks, token type validation, and optional mTLS for service-to-service. This directly strengthens API2.<sup>[39]</sup>
- Centralize authorization: Use ABAC/RBAC policy engines (e.g., OPA, Cedar) and bind FUNCTION\_ROLE\_MAP/OBJECT\_OWNERSHIP\_FIELDS/PROPERTY\_ACL to policy decisions and attribute stores, strengthening API1/API3/API5.<sup>[39]</sup>
- Distributed rate limiting: Back token buckets with Redis and add concurrency caps, timeouts, circuit breakers, and per-scope weights; apply separate budgets to expensive

downstream integrations to limit cost amplification (API4).<sup>[39]</sup>

- Stronger anti-automation: Add device fingerprinting, risk scoring, progressive challenges, and anomaly detection for sensitive flows to reduce business flow abuse (API6).<sup>[39]</sup>
- Harden SSRF further: Add DNS rebinding protections, forbid redirects to private IPs, normalize/resolve IPv6 and dotless hosts, and pin to allow-listed netblocks if feasible (API7).<sup>[39]</sup>
- Automate inventory: Generate DOCUMENTED\_ENDPOINTS and request/response schemas from OpenAPI in CI/CD; fail deployments if drift is detected, and set sunset windows for deprecated versions (API9).<sup>[39]</sup>
- Observability: Log denials and decisions with structured fields (principal, route, reason) and feed SIEM/UEBA to detect abuse patterns across API1–API10 categories.<sup>[39]</sup>

This code and configuration scaffold provide a fail-closed, policy-driven approach aligned with the OWASP API Security Top 10 (2023), emphasizing least privilege, explicit allow-listing, and strict validation across the full request/response lifecycle.<sup>[39]</sup>

✱

**soo the owasp top 10 vulnerabilities are common, but when i develop a WAF with pre defined rules, if any attack signatures are detected then it can be blocked, and that same WAF can be put in as a proxy between user and server in almost all web applications, but in case of API security, the API endpoints and all are custom and different for each web application,so how can i develop a WAAP?**

A reusable WAF can block generic web attacks with static signatures, but a WAAP for APIs must be policy-driven and API-aware: it needs your API inventory, schemas, identities, and business logic to enforce per-endpoint authentication, authorization, and usage rules that signatures alone can't capture. The practical way to build a broadly reusable WAAP is to separate the generic controls from API-specific policy and load that policy from specs (OpenAPI), identity providers, and per-service configuration at deploy time.<sup>[67] [68] [69]</sup>

### **Core idea: policy + engine**

- Build a generic enforcement engine (authn, authz checks, schema validation, rate limiting, SSRF egress control, security headers), and keep all API specifics in versioned policies derived from OpenAPI and org standards; at runtime the same engine works for different apps by loading different policies.<sup>[68] [69]</sup>

- Treat the WAAP as a sidecar/gateway pattern: place it between clients and services (or in front of an API gateway) so it can apply identity and schema-aware controls per route, not just regex signatures; this aligns with secure API gateway blueprints. [\[69\]](#) [\[67\]](#)

## What is generic and reusable

- Common OWASP API Top 10 mitigations are reusable: token verification, issuer/audience checks, function/object/property-level authorization hooks, rate limits, payload size/depth caps, SSRF allow-lists, secure headers, deprecations/version gating, and upstream response validation; these are engine capabilities, not per-API logic. [\[68\]](#) [\[69\]](#)
- Deploy pattern: Internet → Edge WAF/WAAP → API Gateway/APIM → Services; edge enforces generic Layer-7 controls, and APIM/WAAP enforces API-aware policies (schemas, roles, quotas) with centralized policies and telemetry. [\[69\]](#)

## What must be per-API policy

- Endpoints and methods: generated from your OpenAPI spec to enumerate documented surfaces, versions, and parameter shapes; everything else falls closed to curb shadow/zombie APIs. [\[68\]](#)
- Schemas: request and response contracts (types, required fields, enums, max sizes) compiled to validators for each operation; this blocks mass assignment and excessive data exposure. [\[68\]](#)
- Authorization matrices: per-operation role/scope rules and object-ownership checks derived from your domain model; this closes BOLA and function-level auth gaps. [\[68\]](#)
- Sensitive flows: identify business-critical operations (payments, ticketing, password reset) and attach anti-automation, stronger quotas, and step-up auth to just those routes. [\[68\]](#)

## How to make it portable across apps

- Spec-driven: ingest OpenAPI at deploy time and auto-generate allow-lists (paths, params), validators, and default rate-limit classes; keep overrides for sensitive flows and admin endpoints; fail deploy if spec and code drift. [\[69\]](#) [\[68\]](#)
- Identity-driven: integrate with your IdP (OIDC/JWKS) and map tokens to roles/scopes/attributes; the engine stays the same while mappings differ per tenant/app. [\[69\]](#) [\[68\]](#)
- Policy bundles: ship policies as versioned bundles (YAML/JSON) that declare per-route auth, quotas, and SSRF egress rules; the same WAAP binary can load different bundles at startup or via control plane. [\[67\]](#) [\[69\]](#)
- Reference blueprint: follow a secure API gateway blueprint with threat modeling, policy enforcement points, and CI/CD checks so each app onboards by providing spec + policy, not code changes. [\[67\]](#)

## Minimal architecture

- Control plane: stores OpenAPI specs, policy bundles, JWKS metadata, and distributes compiled policies to gateways; also runs CI validation. [\[67\]](#) [\[69\]](#)
- Data plane: stateless WAAP instances that enforce policies: TLS termination, token checks, schema validation, rate limiting, SSRF guard, security headers, and logging; can run as ingress, sidecar, or gateway plugin. [\[69\]](#)
- Observability: structured logs and metrics per route and decision (allow/deny/reason) for forensics and tuning; feed SIEM and anomaly detection for business logic abuse. [\[69\]](#)

## Concrete build plan

- Start with an engine like the Python middleware shared earlier, but replace hardcoded maps with hot-loaded policies compiled from OpenAPI and YAML; add a loader that watches a policy store and rebuilds validators and route tables on the fly. [\[68\]](#)
- Implement policy objects: Routes (method, path template), Schemas (compiled from OpenAPI), AuthZ (RBAC/ABAC rules), Quotas (per role/route), SensitiveFlows, EgressRules (allow-lists), Versions (active/deprecated), and DefaultDeny. [\[68\]](#)
- Provide adapters: FastAPI/Starlette, Flask, ASGI, and Envoy/NGINX plugin variants so the same logic runs at different layers; this mirrors vendor blueprints pairing WAF + APIM. [\[69\]](#)
- Add discovery guardrails: only publish and allow routes present in the spec; tag deprecated operations with sunset dates; block undocumented parameters; inventory is a first-class control against API9. [\[68\]](#)

## Why signatures alone aren't enough for APIs

- Many API risks are authorization and workflow issues (BOLA/BFLA, sensitive business flows) that don't present unique payload signatures; they require identity, object ownership, and rate/sequence analysis per operation, which is inherently policy-driven. [\[68\]](#)
- Unsafe consumption of third-party APIs and SSRF require outbound validation and schema checks, not inbound signatures; a WAAP must validate destinations and upstream responses. [\[68\]](#)

## Deployment patterns that work

- Edge WAF + APIM: Edge blocks common web exploits; APIM/WAAP enforces API-aware policies (rate by key, private networking, bot protection), a pattern documented in platform architectures. [\[69\]](#)
- Gateway + WAAP synergy: Combine API gateway traffic management with WAAP threat detection and business logic abuse defenses to cover gaps across layers. [\[70\]](#) [\[69\]](#)

## First steps to implement

- Standardize: require every team to maintain OpenAPI with security schemes and object identifiers; enforce CI linting and publish to the control plane.<sup>[68]</sup>
- Automate compilation: turn OpenAPI into validators and route maps; generate default deny policies; require explicit approvals for sensitive flows and egress hosts.<sup>[68]</sup>
- Integrate IdP: enable JWKS rotation, token introspection, and scope mapping; default-deny anonymous access unless marked public.<sup>[69] [68]</sup>
- Instrument and iterate: monitor denials and anomalies; tune quotas and anti-automation where abuse appears; sunset deprecated versions per policy.<sup>[69] [68]</sup>

Bottom line: design the WAAP as a reusable engine plus per-app policy generated from OpenAPI and identity mappings; deploy it as a gateway/sidecar that enforces object-, property-, and function-level rules, resource controls, SSRF egress allow-lists, and versioned inventories so it adapts to each application without rewriting code. This aligns with OWASP API Top 10 guidance and secure API gateway blueprints used in production architectures.<sup>[67] [69] [68]</sup>

✱

## **i need to develop a global and common API ,not a per APP one, so give me the vulnerabilities that it can address and give me python code of that WAAP module.**

A single, global WAAP can only enforce controls that are API-agnostic: identity/authentication checks, default-deny surfaces, generic authorization patterns, schema conformance from specs, abuse throttling, SSRF-safe egress, security headers, and upstream response validation. These map to OWASP API Top 10 risks that do not require per-app business logic: API2 (authn), API4 (resource consumption), API6 (flow abuse throttling), API7 (SSRF), API8 (misconfiguration), API9 (inventory/versioning), and API10 (unsafe consumption); API1, API3, and API5 can be covered generically by pattern- and spec-driven policies (e.g., per-route ownership and role gates) when the WAAP loads OpenAPI and IdP metadata at deploy time.<sup>[98] [99] [100] [101]</sup>

## Vulnerabilities addressed globally

- Broken Authentication (API2): Enforce OIDC/JWKS token validation, issuer/audience checks, token age and revocation; default-deny unauthenticated calls except explicitly public operations.<sup>[99] [98]</sup>
- Unrestricted Resource Consumption (API4): Per-identity rate limiting, quotas, payload size/depth/array caps, timeouts, and concurrency limits to prevent DoS and cost spikes.<sup>[102] [98]</sup>
- Unrestricted Access to Sensitive Business Flows (API6): Route tagging for flows like payments or password reset with higher throttles, anomaly/bot heuristics, and optional step-up auth.<sup>[100] [98]</sup>

- Server-Side Request Forgery (API7): Outbound allow-list by host/scheme, private IP/DNS-rebinding protection, strict redirect policy, and per-integration egress keys. [\[98\]](#)
- Security Misconfiguration (API8): Secure defaults: TLS, strict methods, header hardening, strict JSON parsing, parameter validation from spec, and default-deny for undocumented routes. [\[103\]](#) [\[98\]](#)
- Improper Inventory Management (API9): Version gating, deprecation blocks, only documented endpoints from OpenAPI are exposed; shadow/zombie endpoints 404/410. [\[99\]](#) [\[98\]](#)
- Unsafe Consumption of APIs (API10): Validate third-party responses against schemas, enforce timeouts/retries, minimize data, and isolate partner traffic. [\[103\]](#) [\[98\]](#)
- Partially generic coverage for BOLA/BFLA/Property-level (API11/5/3): Apply spec-driven role/scope checks and object-ownership hooks based on a standard resource model (owner\_id in path/body), then let apps optionally extend; many APIs benefit without per-app code. [\[100\]](#) [\[98\]](#)

## Global Python WAAP module (ASGI/FastAPI adapter)

This module is policy-driven and loads OpenAPI-derived routes/schemas plus IdP settings. Drop it in front of diverse APIs; per-app specifics come from the supplied spec/policy file, not code.

```
# pip install fastapi uvicorn pydantic httpx pyjwt cryptography
import json, time, ipaddress, hashlib, re
from typing import Dict, Any, Optional, Tuple, Set
from urllib.parse import urlparse

import httpx, jwt
from fastapi import FastAPI, Request
from fastapi.responses import JSONResponse
from pydantic import BaseModel, ValidationError

# ---- Control plane-fed policy (replace loader to read OpenAPI + YAML) ----
class Policy(BaseModel):

```

## How this global module maps to OWASP API Top 10

- API2 Broken Authentication: OIDC/JWT verification with issuer/audience/expiry and default-deny on protected routes. Replace decode stub with JWKS verification per issuer. [\[98\]](#) [\[99\]](#)
- API4 Unrestricted Resource Consumption: Token-bucket rate limiting per identity+path; caps on payload size, JSON depth and item counts. [\[102\]](#) [\[98\]](#)
- API6 Unrestricted Access to Sensitive Business Flows: Tag sensitive routes in policy and apply extra throttling/heuristics. [\[100\]](#) [\[98\]](#)
- API7 SSRF: SafeEgress class enforces outbound allow-list and blocks private IP/DNS tricks. [\[98\]](#)
- API8 Security Misconfiguration: Deny risky methods, strict header hardening, strict JSON parsing, and reject suspicious query keys. [\[103\]](#) [\[98\]](#)
- API9 Improper Inventory Management: Only serve requests for versions and endpoints declared in policy (typically compiled from OpenAPI); unknown or deprecated versions return 404/410. [\[99\]](#) [\[98\]](#)
- API10 Unsafe Consumption: Validate upstream responses, enforce timeouts, and minimize returned data. [\[103\]](#) [\[98\]](#)

- API1/3/5 Partial generic coverage: Optional policy keys enable route RBAC and a simple ownership check when resource IDs are in paths; for richer models, apps can extend via attributes/scopes while reusing the same engine.<sup>[100] [98]</sup>

This design stays global by keeping the enforcement engine generic while loading API-specific facts (routes, versions, public operations, optional RBAC and ownership hints) from a policy file derived from each API's OpenAPI, enabling common protections without embedding per-app business logic.<sup>[101] [99] [98] [100]</sup>
